A purely numerical method, *Direct Computation Method* is applied to evaluate Feynman integrals. This method is based on the combination of an efficient numerical integration and an efficient extrapolation. In addition, high-precision arithmetic and parallelization technique can be used in this method if required. We present the recent progress in development of this method and show results such as one-loop 5-point and two-loop 3-point integrals.

ACAT2008

XII International Workshop on Advanced Computing and Analysis Techniques in Physics Research

Erice, Sicily, Italy

November 3-7, 2008

^{*}Speaker.

1. Introduction

This paper describes a computational method for the loop integrals. This method is named as *Direct Computation Method* and its advantage is handling singularities in a purely numerical way which appear in the denominator of the integrand. We have already computed several diagrams with one-loop and two-loop such as

- One-loop vertex and box diagrams with/without infrared divergence[1, 2, 3, 4],
- Two-loop planar and non-planar vertex diagram[5].

In this paper, we present the brief description of this method and show another examples of loop integrals.

2. Direct Computation Method

This method is based on a numerical multi-dimensional integration to get the sequence of the integration approximations of the loop integral, $\{I(\varepsilon_l)\}$, $l = 0, 1, 2, \dots$, and an extrapolation technique for the convergence of the sequence. Here, the sequence of $\{\varepsilon_l\}$, $l = 0, 1, 2, \dots$ is given as $\varepsilon_l = \varepsilon_0 \times a^{-l}$ and ε_0 and a are real constants such as 256 and 2 respectively[1]. When we take the limit of $\varepsilon \rightarrow 0$, we get the result of the loop integral.

In *Direct Computation Method*, the integration routine plays a central role. We have been using two different integration routines, DQAGE and DE. The former, DQAGE, is an adaptive algorithm routine in QUADPACK [6]. We call the combination of DQAGE and the extrapolation technique *DQ-Direct Computation Method* in this paper. The latter, *Double Exponential formulas*[7], shortly DE, uses $\tanh(\pi/2 * \sinh(t))$ transformation for numerical integration. We call the combination of DE and the extrapolation technique *DE-Direct Computation Method* in this paper.

For both integration routines, we are combining Wynn's ε algorithm [1, 8] or Aitken extrapolation to accelerate the convergence.

3. Examples of the Computation

3.1 One-loop box contributing to $gg \rightarrow b\bar{b}H$

The first example is the one-loop box diagram with complex masses contributing to $gg \rightarrow b\bar{b}H$ in Fig. 1. In the computation we

Figure 1: Box diagram contributing to $gg \rightarrow b\bar{b}H$

take $\sqrt{s} = 353 \text{ GeV}$ as an example and we fix $\sqrt{s_1} = \sqrt{2(m_t^2 + M_W^2)} \approx 271.06 \text{ GeV}$. As for the mass parameters, $m_t = 174 \text{ GeV}$, $M_W = 80.3766 \text{ GeV}$ and $M_H = 165 \text{ GeV}$. We introduce the complex masses as $m_t^2 \rightarrow m_t^2 - im_t\Gamma_t$ and $M_W^2 \rightarrow M_W^2 - iM_W\Gamma_W$ with $\Gamma_t = 1.5 \text{ GeV}$ and $\Gamma_W = 2.1 \text{ GeV}$. The results of the numerical computation agree perfectly to the analytic results reported by L. D. Ninh *et al.* [9] as in Fig. 2 and Fig. 3.

3.2 $e^+e^- \rightarrow ZZ \rightarrow e^+e^-Z$

The second example is the one-loop pentagon diagram in Fig. 4. The loop integral is

$$I = \int_0^1 dx_1 dx_2 dx_3 dx_4 dx_5 \delta(1 - \sum_{i=1}^5 x_i) \frac{1}{D^3}. \quad (3.1)$$

Here, $D(\mathbf{x})$ is given as

$$D(\mathbf{x}) = \sum_{i=1}^5 m_i^2$$

Figure 2: Integration result of the real part with complex masses as a function of $\sqrt{s_2}$. Our results agree to the 5- or 6-digit accuracy of Ninh's.

Figure 3: Integration result of the imaginary part with complex masses as a function of $\sqrt{s_2}$. Our results agree to the 4-, 5- or 6-digit accuracy of Ninh's.

$$\begin{aligned}
 & -x_1x_2s_1 - x_2x_3s_2 - x_3x_4s_3 - x_4x_5s_4 \\
 & -x_5x_1s_5 - x_1x_3s_{12} - x_2x_4s_{23} - x_3x_5s_{34} \\
 & -x_4x_1s_{45} - x_5x_2s_{51}, \quad (3.2)
 \end{aligned}$$

where $m_1 = m_3 = m_4 = 0.5 \times 10^{-3}$ GeV and $m_2 = m_5 = 91.00$ GeV. As an example, one numerical result is shown in Table 1 with a set of parameters corresponding to one phase space point (Table 2). These agree to the results by T. Ueda *et al.* [10]. The elapsed time for the computation is about 9.3 hours for the real part using AMD Opteron 2.2 GHz CPU.

3.3 Two-Loop Self-energy

The third example is the two-loop self-energy

Figure 4: Diagram of $e^+e^- \rightarrow ZZ \rightarrow e^+e^-Z$

Table 1: Numerical result of one-loop pentagon.

	Result	Error
real	$0.4118519 \times 10^{-13}$	0.410×10^{-17}
imag.	$-0.2336871 \times 10^{-12}$	0.619×10^{-16}

Table 2: A set of parameters corresponding to one phase space point

Parameter	value
S_{12}	100000.00000
S_{15}	-14146.0960752976
S_{23}	-30471.3126018059
S_{34}	32384.1496580698
S_{45}	37833.5682283554

diagram in Fig. 5.

The formulae of the loop integral is [11]

$$(16\pi^2)^2 I = \int_0^1 dx_1 dx_2 dx_3 dx_4 dx_5 \delta\left(1 - \sum_{i=1}^5 x_i\right) \frac{1}{CD}. \quad (3.3)$$

Here, $D(\mathbf{x})$ is given as

$$\begin{aligned}
 D(\mathbf{x}) = & -p^2(x_5(x_1 + x_3)(x_2 + x_4) \\
 & + (x_1 + x_2)x_3x_4 + (x_3 + x_4)x_1x_2) \\
 & + C\tilde{M}^2, \quad (3.4)
 \end{aligned}$$

$$C = (x_1 + x_2 + x_3 + x_4)x_5 + (x_1 + x_2)(x_3 + x_4),$$

Figure 5: Diagram of the two-loop self-energy

$$\tilde{M}^2 = \sum_{i=1}^5 x_i m_i^2. \quad (3.5)$$

We show the numerical results with two sets of the mass assignment shown in Table 3. The results with the first set are compared with ones by Kreimer [12] and by Kurihara *et al.* [13] in Fig. 6. The results with the second set are compared with ones by Kurihara *et al.* [13], by Bauberger *et al.* [14] and by Passarino *et al.* [15] in Fig. 7. In this computation, the elapsed time for the computation becomes longer around the singularities.

Table 3: Set of mass assignment in GeV

Set#	m_1	m_2	m_3	m_4	m_5
1	150.0	150.0	150.0	150.0	91.17
2	$\sqrt{1.0}$	$\sqrt{2.0}$	$\sqrt{4.0}$	$\sqrt{5.0}$	$\sqrt{3.0}$

Figure 6: Numerical results of the loop integral with Set#1 mass assignment as a function of $p^2/150.0^2$. The results of [12, 13] are divided by the value of p^2 .**Figure 7:** Numerical results of the loop integral with Set#2 mass assignment as a function of p^2 . The sign of our numerical results is conformed to [13, 14, 15].

4. Parallel Computation

As we have described, the elapsed time for the computation becomes longer to get the sequence $\{I(\epsilon_l)\}$ in a good accuracy when the singularity becomes steeper. To reduce the computation time, parallel computing technique is often used. We have developed the parallel code of *Direct Computation Method*. We used MPI¹ library which is widely used in the parallel computing environment. We evaluated the speedup of the parallel code of *DQ* - and *DE- Computation Method* taking the integrals of two-loop vertex and one-loop box diagram as examples. The results of the speedup are shown in Table 4, Fig. 8 and Fig. 9. Both parallel codes show a good speedup behavior.

5. Summary

In this paper, we presented several numerical results of the loop integrals by *Direct Computation Method*. This method is based on the combination of the numerical integration and an extrapolation technique. To reduce the computation time we developed the parallel code

¹Message Passing Interface

Table 4: Speedup of the parallel code of *DQ-Direct Computation Method* for the two-loop vertex diagram with singularities. We use PPC 970 and PC farm for the measurement. PPC 970 is IBM Blade CenterJS20 with PowerPC 970 2.2 GHz CPUs. PC farm consists of 16 Intel Xeon 3.06 GHz CPUs.

# of CPUs	PPC 970	PC farm
1	1.00	1.00
2	1.53	1.50
4	2.99	2.54
8	5.50	4.54
16		13.31

Figure 8: Speedup of the parallel code of *DE-Direct Computation Method* for the one-loop box integral with (DE-xd1-s-positive) and without (DE-xd1-s-negative) singularities. We use CRAY XD1 for the measurement.

Figure 9: Speedup of the parallel code of *DE-Direct Computation Method* for the one-loop box integral with (DE-bg-s-positive) and without (DE-bg-s-negative) singularities. We use IBM BlueGene/L at KEK for the measurement.

and the results of the speedup measurement are also shown.

Acknowledgments

We wish to thank Dr. Kurihara and Prof. Kaneko for their valuable suggestions. We wish to thank Prof. Kawabata for his support. This work is supported in part by the project of Hayama Center for Advanced Studies at the Graduate University for Advanced Studies.
